

Base from U.S. Geological Survey 1:63,360, 1958
Topography by photogrammetric methods from aerial
photographs taken in 1952

Surficial geology mapped chiefly by L. A. Yehle using year 1952 airphotos. Field checked by L. A. Yehle, H. R. Schmoll, and A. F. Chleborad, 1978, 1979, and 1980; assisted by J. M. Core, 1978, and C. A. Gardner and A. D. Pasch, 1979 and 1980.

PRELIMINARY SURFICIAL GEOLOGIC MAP OF THE SOUTHEASTERN PART OF THE TYONEK B-5 QUADRANGLE, SOUTH-CENTRAL ALASKA

By
Lynn A. Yehle, Henry R. Schmoll, and Alan F. Chleborad

INTRODUCTION
The Tyonek B-5 quadrangle lies about midway between Cook Inlet and the Tordillo Mountains (index map) whose southern peak is the active volcano, Mount Spurr, 3,375 m high. For presentation of our surficial geologic information, we divided the map into three parts; the southwestern and northern parts are described respectively on companion maps (Yehle, Schmoll, and Chleborad, 1983; Yehle, Schmoll, and Gardner, 1983). In the southeastern part, wholly within the Kenai Peninsula Borough, the broad flood plain of the Chichantna River bisects the area and is dominated by meltwater from retreating Capps Glacier whose estimated 1983 terminus is about 2.8 km west of the west boundary of the map area. Other major physiographic elements include the gently sloping flanks of the Chichantna valley and a north-facing escarpment near the south shore of Beluga Lake (fig. 1). A variably thick mantle of organic material (late Pleistocene) volcanic ash forms an irregular cover over most of the land surface and is generally less than 1 m in thickness. Only on very steep slopes and on flood plains of active streams is the mantle not present. The ash originated from Mount Spurr as well as from other volcanoes in the region (Riethel, 1983). Significant glacial features and deposits include the Denzlow Lake lateral moraine of late Pleistocene age and the Chichantna end and lateral moraines of early(?) Holocene age; the relationship of these moraines to regional glacial geology is outlined in Schmoll and Yehle (1983). Landslides, including a major complex of massive slides along the south flank of the Chichantna valley, are very common and many of them formed in claystone and siltstone of the Tertiary Tyonek Formation. Bedrock of the Tyonek Formation probably underlies the northern part of the map area where bedrock is too poorly exposed to show on the generalized map of published bedrock data (fig. 2). Other bedrock types include pebbly sandstone and pebble conglomerate of the Tertiary West Foreland Formation; both of these rock types are well exposed locally in the southeastern part of the area (fig. 2).

DESCRIPTION OF MAP UNITS
The map delineates deposits considered to be about 1 m or more in thickness. Thicknesses given for deposits generally are estimates based on field observations. Grain sizes of unconsolidated particles described follow the classification of Wentworth (1922). Standard age symbols are omitted from map symbols because all units except bedrock and volcaniclastic strata are entirely of Quaternary age.

MORaine DEPOSITS
Till, primarily diamictic, consisting of gravely, sandy silt and variable amounts of clay; clasts as large as boulders. Chiefly unsorted, but locally moderately well sorted as discontinuous lenses of sand to sandy pebble gravel. Variably compact. Formed into ridges, hummocky ground, and some relatively smooth plains. As mapped, includes scattered bedrock exposures too small to show at 1:31,680 scale.

END- AND LATERAL-MORaine DEPOSITS—Chiefly diamictic formed into heterogeneous assemblage of moderate-relief landforms some of which are steep-sided ridges and shown on map as lineaments. Diamictic may contain a high percentage of coarse sand and silt. As mapped, includes some ground-moraine, ice-contact, outwash, pond, alluvial, and organic deposits. Thickness probably less than 25 m.

Outer lateral-moraine deposits the Denzlow Lake moraine (late Pleistocene)—In well-marked belt of moraines outmost from the Chichantna River valley. Best portrayed directly northeast of Chuit Creek. Traceable east-southwest from mapped area to Denzlow Lake (index map) and beyond. This moraine, informally named the Denzlow Lake moraine, was previously termed the Carlson Lake moraine (Schmoll and others, 1981). Age assignment is tentative and based on similarity with morphology of the Elmendorf Moraine at Anchorage, Alaska, which is age bracketed by ¹⁴C dated geologic materials as younger than about 14,000 and older than about 12,000 yr B.P. (Schmoll and others, 1979).

Chiefly lateral- and medial-moraine deposits related to the Denzlow Lake moraine (late Pleistocene)—Deposits mostly in positions recessional to outer lateral-moraine deposits (meo). In single and multiple landforms and discontinuous segments northeast of Chuit Creek and on broad ridge north of floor of Chichantna River valley. Moraines are fully vegetated and most have gentle crests and are only moderately modified by erosion. Bogs partly fill many small ponds.

MORaine DEPOSITS
mh HUMMOCKY MORaine DEPOSITS (LATE PLEISTOCENE)—Diamictic forming landforms having uneven surface topography and very little or no linear continuity. Diamictic may contain a high percentage of coarse clasts. Deposits scattered throughout most of mapped area. Thickness probably as much as 10 m.

GROUND-MORaine DEPOSITS—Form mostly low, rolling mounds on gentle to moderate regional slopes or on plains of low relief. Ground-moraine deposits near or within moraine topography across Chichantna River (early? Holocene)—Thickness probably less than 7 m.

Deposits consisting of ground moraine or mostly ground moraine and related to the Denzlow Lake moraine.

mg GROUND-MORaine DEPOSITS northeast of Chuit Creek and on broad ridge north of the floor of Chichantna River valley (late Pleistocene)—Thickness probably less than 7 m.

Thin ground-moraine deposits—Thickness probably averages 2 m. As mapped, includes locally common bedrock exposures. Widely distributed northeast of Chuit Creek and north of Chichantna River valley.

mf MORaine DEPOSITS in drumlin and fluted landforms (late Pleistocene)—Composed mostly of ground-moraine deposits modified by glacier ice. Located chiefly in central and eastern part of area. Thickness probably less than 10 m.

Extensively dissected moraine deposits (late Pleistocene)—In areas where deposits are extensively cut by very numerous narrow, shallow gullies; gullies probably range in depth from 1 to 4 m. Some gullies expose bedrock along their margins; most streams in the gullies are intermittent. Thickness probably less than 5 m. Located south of Beluga Lake. Includes some alluvial and colluvial deposits too small to show at 1:31,680 scale.

Thin extensively dissected moraine deposits—Probably average 2 m in thickness. As mapped, includes locally common bedrock exposures. Located chiefly in headwaters of Chichantna Creek. Channelled moraine deposits (late Pleistocene)—Areas of chiefly ground moraine containing to many abandoned glacial-meltwater channels that they are too numerous or small to show individually at 1:31,680 scale. Most channels approximately parallel to topographic contours and range in depth from 2 to 10 m. Some channels exhibit bedrock along their margins. Selected channels shown on map. Located principally on moderate to steep slopes of Beluga Lake and the floor of Chichantna River valley. Includes some outwash-channel and overlying organic deposits. Thickness probably less than 5 m.

Probably average 2 m in thickness—As mapped, includes locally common bedrock exposures. Located chiefly near headwaters of Chichantna and Bishop Creeks.

om OLD MORaine DEPOSITS (PLEISTOCENE)—Consists mostly of ground moraine. Generally thinner than other ground moraine, probably averaging 3 m, and locally covered by as much as 1 m of organic material and volcanic ash. Widely distributed southwest of Chuit Creek.

Thin olivine deposits—Thickness probably averages 2 m. As mapped, includes locally common bedrock exposures. Widely distributed southwest of Chuit Creek.

KAME AND OTHER ICE-CONTACT DEPOSITS
ma Mostly gravely sand and some gravelly, silty sand and diamictic in landforms ranging from irregularly shaped lanes to narrow and sinuous eskers. Most deposits loose, some relatively compact. Thickness probably less than 15 m.

hk DEPOSITS RELATED TO THE CHICHANTNA MORaine (EARLY HOLOCENE)—Most deposits on or adjacent to floor of valley.

DEPOSITS RELATED TO DENZLOW LAKE MORaine (LATE PLEISTOCENE)—Scattered distribution northeast of Chuit Creek. Good examples of deposits in secs. 27 and 28, T. 14 N., R. 13 W.

OUTWASH DEPOSITS
Mostly bedded sandy gravel and sand formed by glacial meltwaters on wide, low-gradient plains or in small, generally narrow, diamictic- or bedrock-bounded valleys most of which are approximately parallel to topographic contours. Most deposits loose and moderately well sorted; commonly more gravely at depth. Active modern outwash distal to glacier is mapped as flood-plain alluvial deposits (ap).

yo DEPOSITS OF THE LOWERMOST VEGETATED OUTWASH PLAIN OF THE CHICHANTNA RIVER VALLEY (LATE HOLOCENE)—Deposited by meltwater from young advance of Capps Glacier, represented by a moraine directly west of mapped area. Thickness possibly as much as 20 m.

DEPOSITS DOWNVALLEY FROM THE CHICHANTNA MORaine (EARLY HOLOCENE)—Thickness possibly as much as 25 m.

oc OUTWASH-CHANNEL DEPOSITS RELATED TO THE DENZLOW LAKE MORaine (LATE PLEISTOCENE)—Distributed throughout area except in central and central western parts. Commonly overlain by pond or organic deposits. Thickness possibly as much as 5 m.

ot OUTWASH-TERRACE DEPOSITS RELATED TO THE DENZLOW LAKE MORaine (LATE PLEISTOCENE)—Remnants of former outwash plains which presently are at least several meters higher than adjacent outwash or other fluvial deposits. Mainly in central eastern part of area. Thickness probably less than 5 m.

ALLUVIAL DEPOSITS
a ALLUVIAL DEPOSITS, UNDIVIDED (HOLOCENE)—Mostly pebbly sand to cobble gravel deposited by small, medium, and some large streams of low to moderate gradient; includes deposits in low terrace, beach, and moderately well sorted within beds. Distributed throughout area. Thickness possibly as much as 15 m.

af FINE-GRAINED ALLUVIAL DEPOSITS (HOLOCENE)—Chiefly sand and some small pebbles, silt, and organic materials deposited by small, generally low gradient streams. Commonly uniformly bedded. Present at and near base of many short slopes throughout area. Thickness probably less than 5 m.

ap FLOOD-PLAIN ALLUVIAL DEPOSITS (HOLOCENE)—Mostly pebbly to cobble gravel and sand forming most of the presently active flood plain and lowest generally unsorted terraces of the large Chichantna River. Well bedded and commonly well sorted within beds. Within the terrace, coarsest material generally at depth. Higher terraces herein mapped as outwash deposits related to young advance of Capps Glacier (yo). Deposits chiefly from sediment-laden meltwater from Capps Glacier directly west of mapped area. Thickness possibly as much as 20 m.

f ALLUVIAL-FAN DEPOSITS (HOLOCENE)—Mostly gravel and gravely sand deposited by active, generally steep gradient streams. Commonly irregularly bedded; poorly to moderately well sorted within beds. Several deposits near south shore of Beluga Lake and south of floor of Chichantna River valley. Thickness possibly as much as 15 m.

COLLUVIAL AND LANDSLIDE DEPOSITS
ca COLLUVIAL DEPOSITS OF COLLUVIUM AND MOSTLY FINE-GRAINED ALLUVIUM (HOLOCENE)—In areas where colluvial deposits are crossed by so many small watercourses and their alluvial deposits that the alluvial deposits are too numerous to map separately at 1:31,680 scale. Slopes generally moderate. Scattered throughout mapped area, except on floor of Chichantna River valley, although several deposits adjacent to the floor. Probably includes some soil inflection deposits. Thickness possibly as much as 5 m.

c COLLUVIAL DEPOSITS, UNDIVIDED (HOLOCENE AND PLEISTOCENE)—Sources of deposits are both bedrock and unconsolidated materials. Mostly on relatively steep to moderate slopes, notably along present or abandoned stream courses throughout mapped area, except in central and west-central parts. Thickness probably less than 5 m.

cb COLLUVIAL DEPOSITS DERIVED CHIEFLY FROM BEDROCK (HOLOCENE AND PLEISTOCENE)—In steep to moderately steep bluffs adjacent to present or abandoned stream courses. As mapped, locally includes numerous bedrock outcrops. Loose to compact. Thickness probably less than 2 m.

cu COLLUVIAL DEPOSITS DERIVED CHIEFLY FROM UNCONSOLIDATED MATERIALS (HOLOCENE AND PLEISTOCENE)—Mostly on moderate to relatively steep slopes near the Chichantna River. Thickness probably less than 5 m.

cl LANDSLIDE DEPOSITS, UNDIVIDED (HOLOCENE AND PLEISTOCENE)—Deposits scattered throughout area except on floor of Chichantna River. Thickness possibly as much as 100 m. Queried where identity is somewhat uncertain.

clb BLOCK-SLIDE DEPOSITS (HOLOCENE AND PLEISTOCENE)—Deposits showing very slight to moderate spreading of origin on ground surface. The present surface gives appearance of no more than a moderate amount of disintegration of origin; some blocks are of very large size, a few having surface dimensions of about 0.5 by 0.5 m. Well exhibited near Capps Creek and south of Beluga Lake. Thickness of most blocks probably less than 60 m but some possibly as much as 100 m.

clc Fragmented block-slide deposits (Holocene and Pleistocene)—Most deposits consist of blocks that formerly were much larger but now are broken apart and spread out because of continued movement. Deposits scattered throughout area but principally near Capps Creek. Thickness probably less than 15 m.

cls SLUMP DEPOSITS (HOLOCENE AND PLEISTOCENE)—Deposits that appear to have rotated at least several degrees from a vertical plane, slid downslope, and then variably spread out. Deposits scattered throughout area except on floor of Chichantna River valley. Thickness probably less than 60 m.

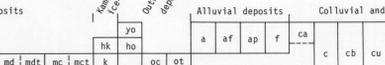

clid DEBRIS-FLOW, MUDFLOW, AND DEBRIS-AVALANCHE DEPOSITS (HOLOCENE AND PLEISTOCENE)—Landslide deposits that probably formed by flowage of parent material. Found throughout area except on floor of Chichantna River valley. Probably less than 5 m in thickness.

LACUSTRINE DEPOSITS
da DELTA DEPOSITS—Mostly pebbly gravel and sand. Deposited in Beluga Lake by Triumvirate south river and by Chichantna River whose delta forms a dam that controls the lake level. Deposits probably finer grained at depth. Thickness possibly as much as 5 m.

db Active delta deposits (Holocene)—Deposited by presently active distributaries of the two deltas.

di Mostly inactive delta deposits (Holocene)—Deposited chiefly by distributaries of former streams. Some delta remnants are as much as 30 m above present lake level.

EMERGED-SHORE DEPOSITS (HOLOCENE)—Pebbly sand and sand and locally some silt deposited at margin of ancestral Beluga Lake as much as 80 m above present lake level. In some places, beach berms and small deltas are well developed. Thickness probably less than 5 m.

af FINE-GRAINED ALLUVIAL DEPOSITS (HOLOCENE)—Chiefly sand and some small pebbles, silt, and organic materials deposited by small, generally low gradient streams. Commonly uniformly bedded. Present at and near base of many short slopes throughout area. Thickness probably less than 5 m.

ap FLOOD-PLAIN ALLUVIAL DEPOSITS (HOLOCENE)—Mostly pebbly to cobble gravel and sand forming most of the presently active flood plain and lowest generally unsorted terraces of the large Chichantna River. Well bedded and commonly well sorted within beds. Within the terrace, coarsest material generally at depth. Higher terraces herein mapped as outwash deposits related to young advance of Capps Glacier (yo). Deposits chiefly from sediment-laden meltwater from Capps Glacier directly west of mapped area. Thickness possibly as much as 20 m.

f ALLUVIAL-FAN DEPOSITS (HOLOCENE)—Mostly gravel and gravely sand deposited by active, generally steep gradient streams. Commonly irregularly bedded; poorly to moderately well sorted within beds. Several deposits near south shore of Beluga Lake and south of floor of Chichantna River valley. Thickness possibly as much as 15 m.

COLLUVIAL AND LANDSLIDE DEPOSITS
ca COLLUVIAL DEPOSITS OF COLLUVIUM AND MOSTLY FINE-GRAINED ALLUVIUM (HOLOCENE)—In areas where colluvial deposits are crossed by so many small watercourses and their alluvial deposits that the alluvial deposits are too numerous to map separately at 1:31,680 scale. Slopes generally moderate. Scattered throughout mapped area, except on floor of Chichantna River valley, although several deposits adjacent to the floor. Probably includes some soil inflection deposits. Thickness possibly as much as 5 m.

c COLLUVIAL DEPOSITS, UNDIVIDED (HOLOCENE AND PLEISTOCENE)—Sources of deposits are both bedrock and unconsolidated materials. Mostly on relatively steep to moderate slopes, notably along present or abandoned stream courses throughout mapped area, except in central and west-central parts. Thickness probably less than 5 m.

cb COLLUVIAL DEPOSITS DERIVED CHIEFLY FROM BEDROCK (HOLOCENE AND PLEISTOCENE)—In steep to moderately steep bluffs adjacent to present or abandoned stream courses. As mapped, locally includes numerous bedrock outcrops. Loose to compact. Thickness probably less than 2 m.

cu COLLUVIAL DEPOSITS DERIVED CHIEFLY FROM UNCONSOLIDATED MATERIALS (HOLOCENE AND PLEISTOCENE)—Mostly on moderate to relatively steep slopes near the Chichantna River. Thickness probably less than 5 m.

cl LANDSLIDE DEPOSITS, UNDIVIDED (HOLOCENE AND PLEISTOCENE)—Deposits scattered throughout area except on floor of Chichantna River. Thickness possibly as much as 100 m. Queried where identity is somewhat uncertain.

clb BLOCK-SLIDE DEPOSITS (HOLOCENE AND PLEISTOCENE)—Deposits showing very slight to moderate spreading of origin on ground surface. The present surface gives appearance of no more than a moderate amount of disintegration of origin; some blocks are of very large size, a few having surface dimensions of about 0.5 by 0.5 m. Well exhibited near Capps Creek and south of Beluga Lake. Thickness of most blocks probably less than 60 m but some possibly as much as 100 m.

clc Fragmented block-slide deposits (Holocene and Pleistocene)—Most deposits consist of blocks that formerly were much larger but now are broken apart and spread out because of continued movement. Deposits scattered throughout area but principally near Capps Creek. Thickness probably less than 15 m.

cls SLUMP DEPOSITS (HOLOCENE AND PLEISTOCENE)—Deposits that appear to have rotated at least several degrees from a vertical plane, slid downslope, and then variably spread out. Deposits scattered throughout area except on floor of Chichantna River valley. Thickness probably less than 60 m.

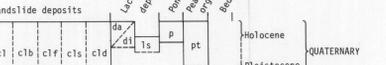

clid DEBRIS-FLOW, MUDFLOW, AND DEBRIS-AVALANCHE DEPOSITS (HOLOCENE AND PLEISTOCENE)—Landslide deposits that probably formed by flowage of parent material. Found throughout area except on floor of Chichantna River valley. Probably less than 5 m in thickness.

LACUSTRINE DEPOSITS
da DELTA DEPOSITS—Mostly pebbly gravel and sand. Deposited in Beluga Lake by Triumvirate south river and by Chichantna River whose delta forms a dam that controls the lake level. Deposits probably finer grained at depth. Thickness possibly as much as 5 m.

db Active delta deposits (Holocene)—Deposited by presently active distributaries of the two deltas.

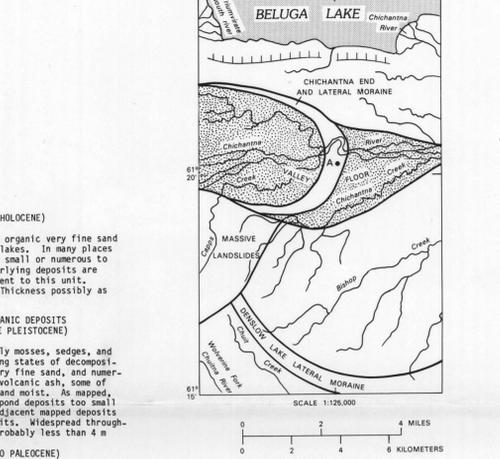

Figure 1.—Selected physiographic and hydrographic features. A site of sample providing date for Chichantna end- and lateral-moraine deposits; major escarpment.

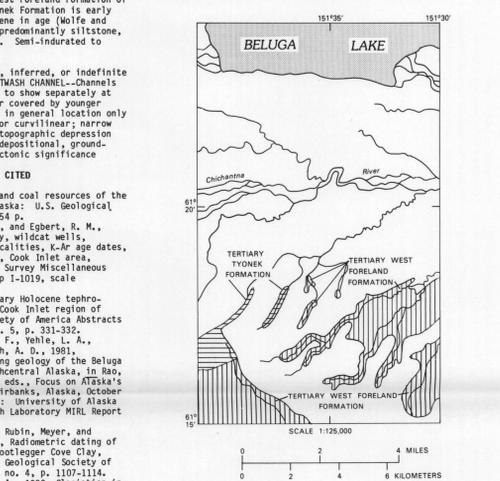

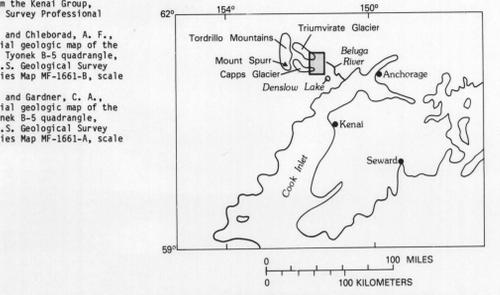

Figure 2.—Generalized bedrock geology from Barnes (1966) and Magoon and others (1976).

INDEX MAP SHOWING LOCATION OF TYONEK B-5 QUADRANGLE (SHADED)

LEGEND
 POND DEPOSITS (HOLOCENE)
 Chiefly organic silt and organic very fine sand adjacent to modern ponds and lakes. In many places includes organic deposits too small or numerous to show at 1:31,680 scale. Underlying deposits are similar to those mapped adjacent to this unit. Widespread throughout area. Thickness possibly as much as 3 m.

PEAT AND OTHER ORGANIC DEPOSITS (HOLOCENE AND LATE PLEISTOCENE)
 Organic materials, chiefly mosses, sedges, and some wood fragments, in varying states of decomposition. Includes some silt, very fine sand, and numerous, commonly thin layers of volcanic ash, some of which are conspicuous. Soft and moist. As mapped, unit in many places includes pond deposits too small to show at 1:31,680 scale. Adjacent mapped deposits extend beneath the peat deposits. Widespread throughout mapped area. Thickness probably less than 4 m.

BEDROCK (MIOCENE TO PALEOCENE)
 In steep to moderately steep bluffs adjacent to stream courses. Some scattered bedrock exposures are present within areas underlain by the colluvial deposits, undivided (c) and colluvial deposits derived chiefly from bedrock (cb), data from Barnes (1966) and Magoon and others (1976) (fig. 2) indicate that rock types include, in order of probable abundance: pebbly sandstone, pebble conglomerate, siltstone, claystone, and some coal beds. The sandstone and conglomerate are within the West Foreland Formation of latest Paleocene age; the Tyonek Formation is early Oligocene through middle Miocene in age (Wolfe and Tanai, 1980) and consists of predominantly siltstone, claystone, and some coal beds. Semi-indurated to indurated.

CONTACT—Approximate, inferred, or indefinite
 ABANDONED GLACIAL OUTWASH CHANNEL—Channels either too small to show separately at 1:31,680 scale or covered by younger deposits. Shown in general location only
 LINEAMENT—Straight or curvilinear; narrow ridge or narrow topographic depression having possible depositional, ground-stability, or tectonic significance
