

OCCURRENCE AND DISTRIBUTION CHART OF OSTRACODES FROM THE
NORTHEASTERN GULF OF ALASKA

By

Elisabeth M. Brouwers

The northeastern Gulf of Alaska, from Montague Island to Cross Sound, (long. 137°W.-148°W., fig. 1) was studied to determine the areas and processes of significant environmental concern to resource development. Samples were collected during three U.S. Geological Survey cruises: F.R.S. Townsend Cromwell cruise EGAL-75-KC and R/V Discoverer cruises DC1-79-EG and DC2-80-EG. Bottom samples were taken by means of a box corer (BC), Shipek (S), or Van Veen (VV) sampling device.

A large number of the bottom-grab samples collected in this study were examined for ostracodes. The ostracode assemblages provide information on the source and age of continental shelf sediments, as well as certain environmental parameters (such as salinity or water temperature) that existed at the time of deposition.

The initial unwashed sample sizes were not standardized and ranged from 200 g to more than 1 kg (wet weight). Sediment was washed on a 200-mesh screen (75 μ m); all of the samples were completely picked of all ostracode valves larger than 180 μ m. Ostracode specimens were identified to the species level wherever possible. All of the valves picked were counted, and the adult and juvenile specimens were differentiated (Brouwers, 1981; 1982; and in press). The numbers on the accompanying charts are derived from these counts, and refer to the total number of valves or recognizable fragments (adult and juvenile counts have been combined on the charts); a carapace is counted as two valves. Specimens with associated chitinous soft parts were noted; these individuals were presumed to be living at the time of collection. An asterisk on the chart indicates that some or all of the specimens of the species from that locality contained soft parts. The table in this pamphlet identifies the location and water depth of each sample.

Of the 150 ostracode species identified, 19 consist of previously described taxa and 131 (87 percent) are new species. New species are referred to by letter designation (for example, Cytheropteron sp. B) or by an affinity to a described species (for example, Cytheropteron aff. C. nodosalatum). Several species could not be placed into the taxonomic concept of described genera. For convenience, each of these species has been placed into the genus to which it is most similar morphologically and noted by quotation marks (for example, "Leguminocythereis" sp. B). These species probably belong to new, undescribed genera.

The charts illustrating each species' occurrence provide information about the total distribution of a species within the study area. The abundance data given for each occurrence provide an approximate indication of how successfully a species is adapting to the physical-chemical parameters at the collection site. These species-distribution patterns may then be compared with the known distributions of particular environmental parameters (for example, bottom water temperature, salinity, dissolved oxygen, nutrients, turbidity, substrate), so that those parameters which influence or control a species distribution can be identified. The establishment of this habitat baseline or datum forms a vital part of the interpretive aspects of Neogene and Quaternary stratigraphic and paleoenvironmental studies in this region. Further, knowledge of these assemblages allows for the definition and characterization of the cold-temperate Aleutian zoogeographic province based on ostracodes. Detailed analyses of the sample species composition will enable recognition of distinct biofaces associations.

Figure 1.--Index map of Alaska showing the region studied in the northeastern Gulf of Alaska.
